

Concurrent Wireless Power Transfer and Motor Drive System with a Single Converter

Enes Ayaz, Oğün Altun, Hakan Polat, Furkan Karakaya, Ozan Keysan

Abstract—This paper presents a novel system to utilize conventional motor drives for wireless power transfer (WPT) to supply auxiliary systems such as IoT devices or sensors in rotating systems. The conventional method is to use a slip ring, which reduces reliability, or to use an extra high-frequency converter next to the motor drive, which increases the system cost. The development of wide-bandgap (WBG) devices such as GaN and SiC transistors has increased the switching frequencies of motor drives with lower switching losses. The voltage harmonics of these high switching frequencies can be utilized to excite a WPT system, while the low-frequency modulated current can still be used to drive the motor. In this paper, the relation between the motor drive and the WPT system is investigated under different operating conditions, and the proposed method is experimentally verified with a GaN-based full-bridge (FB) converter, a series-series (SS) WPT system at 50 W, and a DC motor at 500 W. Thereby, a cost-reduced contactless slip ring was obtained using the concurrent conventional motor drive and IPT systems.

Index Terms—Inductive Power Transfer(IPT), motor drivers, Wireless Power Transfer(WPT), slip rings, rotating systems

I. INTRODUCTION

Power transfer to a rotating frame is required for many applications such as electrical excited synchronous machines [1], radar systems [2], internet of things (IoT) devices [3], sensors [4], etc. Slip rings, consisting of copper rings and carbon brushes in contact with these rings, can be used to excite these systems. However, they are unreliable and require periodic maintenance. Thanks to increased reliability, wireless power transfer (WPT) systems can be an alternative to slip rings [2], [5], [6]. The most common WPT type used for this kind of application is inductive power transfer (IPT) systems, which provide a flexible range of transfer distance with higher efficiencies.

In IPT systems, power is transferred by the magnetic coupling between the transmitter (Tx) and the receiver (Rx) coils, which are loosely coupled, resulting in inherently low power factors. Therefore, compensation circuits, such as two-element (series-series (SS), series-parallel (SP), parallel-parallel (PP), parallel-series (PS)) or hybrid compensation methods (LLC, LCC), are generally used [7]–[9]. Moreover, IPT systems require a high-frequency converter, such as half-bridge (HB) and full-bridge (FB) converters, to excite the Tx coils.

A conventional contactless slip ring using IPT systems is shown in Fig. 1.a. Such systems consist of two separate converters to drive the motor and excite the Tx coil. The

already existing motor drive in these systems generates high-frequency switching voltage harmonics, which are not desired, and attenuated in the motor phase currents due to high motor inductance. In the proposed system, the Tx coil utilizes these high-frequency voltage harmonics to transfer power to the Rx coil, while the low-frequency modulated current is still be used to drive the motor. Thus, a separate IPT converter is no longer required. Since the IPT systems are auxiliary systems (IoT devices, surveillance cameras, radar, sensors, etc.) with power ratings much lower than the motor, conventional motor drives can be used without additional hardware and without increasing the power ratings. Therefore, the complexity and cost of the overall systems are reduced. The proposed system is shown in Fig. 1.b.

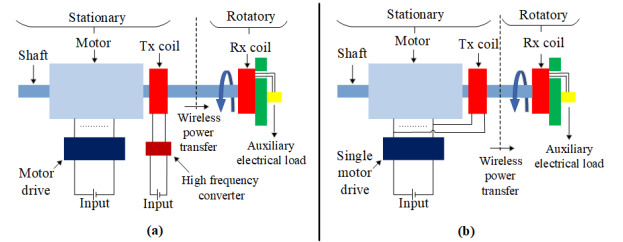

Fig. 1. IPT systems for rotating frames. a) A conventional IPT system. b) The proposed IPT system.

For conventional industrial motor drives, the switching frequency is usually below 20 kHz due to the switching losses of silicon (Si)-based transistors [10]. In this frequency range, IPT systems are not feasible as the Tx-Rx coils get bulkier as the frequency is reduced [11]. However, recent developments in semiconductor technology pave the way for higher switching frequencies (up to several hundred kHz), with Silicon Carbide (SiC) or Gallium Nitride (GaN) based motor drives [12], [13] while still achieving high efficiency [14]. Thus, it is now possible to utilize these high-frequency harmonics for IPT systems. The block diagram of the proposed system is presented in Fig. 2, and the advantages and disadvantages are discussed in Table I. The proposed system meets the requirements and solves the complexity and cost problem of the conventional systems that use two separate converters: one for the motor driver and one for IPT.

In this paper, a DC motor and an SS-IPT will be driven concurrently via a GaN-based FB converter as a proof of concept. The remaining parts of the paper are organized as follows. In section II, the theory of operation will be given for a DC motor and an IPT system. Section III will present the IPT system design steps and considerations. In section

IV, the independent control method for the concurrent motor and the IPT systems. Section V will deliver the experimental results to validate analytical calculations. In Section VI, the system will be compared with existing studies in the literature. Section VII will discuss the hard-ware-free implementation of the IPT system to conventional motor drives.

II. THEORY OF OPERATION

In the proposed system, the motor and IPT systems are concurrently operated by a single FB converter, as shown in Fig. 3. While the motor winding attenuates the high-frequency

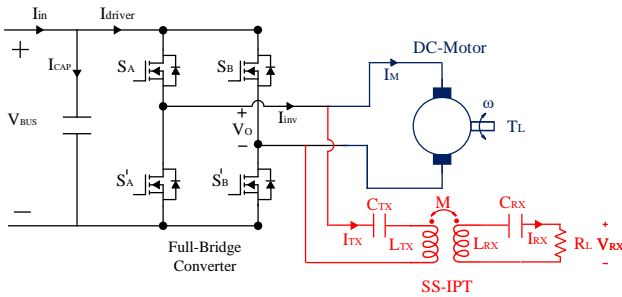

Fig. 3. Circuit diagram of the proposed concurrent motor drive and IPT systems with a single converter.

harmonics in motor current, the IPT systems amplify the switching frequency on the Tx coil. To obtain the desired voltage, an asymmetrical PWM can be used. The switching function is presented in (1), composing of switching frequency (f_s), and duty cycle (D). The harmonic distribution of the converter output voltage for this PWM is given in Fig. 4. The switching frequencies cannot be regulated independently from the DC component, and their magnitude diminishes nearing $D = 0$ and $D = 1$.

$$S(t) = D + \sum_{k=1}^{\infty} \frac{2}{k\pi} \sin(k\pi D) \cos(2\pi k f_s t) \quad (1)$$

Fig. 4. The harmonic distribution of the converter's output voltage, which are obtained by analytically employing the switching function in the FB converter.

The gate signals of top switches of each leg (S_A and S_B), which are used to generate asymmetrical PWM, are represented in Fig. 5. The switching pattern generates a pulsating output voltage (V_o), with a DC and switching components. The motor current (I_M) is mainly DC with small current ripples. The Tx current (I_{TX}) is sinusoidal by assuming that IPT has a high-quality factor. The inverter current (I_{INV}) is the sum of I_M and I_{TX} . However, I_{INV} is dominated by I_M since the IPT system is used for auxiliary systems, which have smaller power ratings than the motor.

Fig. 5. Asymmetrical PWM signals and its corresponding voltage and current waveforms.

III. SYSTEM DESIGN

The specifications of the system are given in Table II. The input voltage is selected as 100 V, and the motor rated power is 500 W while the rated power of the IPT system is 50 W with 20 V output voltage of the receiver side of the IPT system.

A. Motor Drive

The motor drive system includes a separately excited DC machine and a GaN-based FB converter. The FB converter consists of two GaN-based half-bridge boards as details described in [17]. The motor and the drive parameters are given in Table II. Although the motor drive enables to use a switching frequency up to 100 kHz, there are some considerations to select the optimum switching frequency. On the one hand, increasing switching frequency increases the switching losses,

TABLE II
THE SYSTEM INPUT-OUTPUT SPECIFICATIONS AND THE PARAMETERS OF
THE MOTOR AND THE DRIVER.

The Rated Voltages and Powers	
Input Voltage (V_{BUS})	100 V _{DC}
IPT Output Voltage (V_{RX})	20 V _{RMS}
Motor Output Power (P_M)	500W
IPT Output Power (P_O)	50W
The Motor Parameters	
Armature resistance (R_a)	2 Ω
Armature inductance (L_a)	7 mH
Motor electrical time constant (T_s)	3.5ms
The Driver Parameters	
Duty cycle (D)	0.15 – 0.85
Switching frequency (f_s)	< 100 kHz
Switching period (T_s)	> 10 μ s

which reduces the driver's lifetime. On the other hand, decreasing switching frequency increases the current and torque ripples. Moreover, increasing the switching frequency shrinks the passive components of the IPT system but increases the coil losses.

B. Inductive Power Transfer

SS-IPT topology was preferred as the resonant frequency is independent of the load condition and mutual coupling. Since the IPT coils and the motor share the same converter in the proposed system, this independence gives flexibility to the control. The resonant frequency is selected as 65 kHz. Thus, the margin between 65 kHz and 100 kHz is used to control the output voltage by the frequency detuning method. As the motor driver is also used to excite the Tx coil, the input voltage of the IPT system varies between 40 V_{RMS} and 90 V_{RMS} along with the duty cycle. For this reason, the design should be capable of delivering rated power over this wide range of the input voltage. A systematic design is accomplished for the minimum input voltage since the frequency detuning provides the ability to decrease power when the V_o is bigger than it [18]. Firstly, the Rx inductance can be calculated by using (2) where ω_o is the resonant frequency in radian per second, and Q_{RX} is the quality factor, R_L is the load resistance.

$$L_{RX} = \frac{Q_{RX} R_L}{\omega_o} \quad (2)$$

Q_{RX} should be between 2-10 as a rule of thumb [18], [19]. The higher Q_{RX} increases the size of the Rx coil but decreases the size of the Tx coil. Moreover, the mutual inductance can be calculated using (3) where $V_{o,1st}$ is the first harmonic component for the output voltage of the FB converter.

$$M = \frac{V_{RX} V_{o,1st}}{P_o \omega_o} \quad (3)$$

The inductance of the Tx coil can be found using (4). The coupling coefficient (k) varies between 0 and 1.

$$L_{TX} = \frac{V_{o,1st}^2}{k^2 \omega_o^2 Q_{RX}} \quad (4)$$

Finally, the capacitance values can be achieved using (5).

$$C_{TX,RX} = \frac{1}{L_{TX,RX}} \omega_o^2 \quad (5)$$

IPT voltage gain characteristic depends on the selection of k and Q_{RX} . In regular IPT systems, k is limited to provide a bifurcation-free design, guaranteeing ZVS above the resonant frequency. However, ZVS can not be achieved in the proposed system due to the motor's current. Hence, bifurcation-free design is not aimed, and k should be selected considering the Tx coil inductance as shown in Fig. 6.a. Increasing k decreases the size of the Tx coil. Besides, the variations of Tx and Rx inductances as a function of Q_{RX} are shown in Fig. 6.b. Q_{RX} increases the inductance of Rx coil, and the inductance of Tx coil decreases for a constant k . However, Q_{RX} and k also affect the gain-frequency characteristics, as shown in Fig. 6.c.

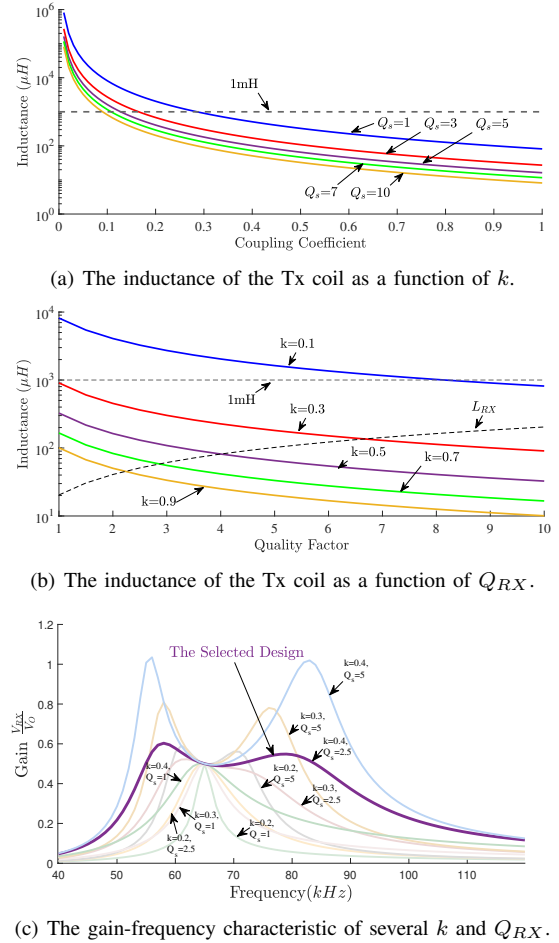

Fig. 6. Effect of the design parameters on Tx coil, Rx coil and gain of the IPT.

Increasing both Q_{RX} and k leads the gain increase at two distinct resonants below and above the resonant frequency. The Q_{RX} and k are selected as 0.40 and 2.6 considering the size of Tx and Rx coils. The voltage gain at the resonant frequency is 0.5. In Table III, the finalized IPT system parameters are presented.

IV. IMPEDANCE MODELLING AND DECOUPLED CONTROL OF THE COMBINED MOTOR AND IPT SYSTEM

Figure 7 shows the lumped circuit of the combined motor and the IPT system. The converter is modeled as a pulsating voltage source.

TABLE III
PARAMETERS OF THE IPT SYSTEM AND THE RESONANCE ELEMENTS.

Receiver quality factor (Q_{RX})	2.6
Resonant frequency (f_0)	65 kHz
Coupling factor (k)	0.40
Load resistance (R_L)	8 Ω
Receiver coil inductance (L_{RX})	51 μ H
Mutual inductance (M)	41 μ H
Transmitter coil inductance (L_{TX})	205 μ H
Receiver resonant capacitance (C_{TX})	115 nF
Transmitter resonant capacitance (C_{RX})	29 nF
Airgap	10 mm
Coil diameter	110 mm

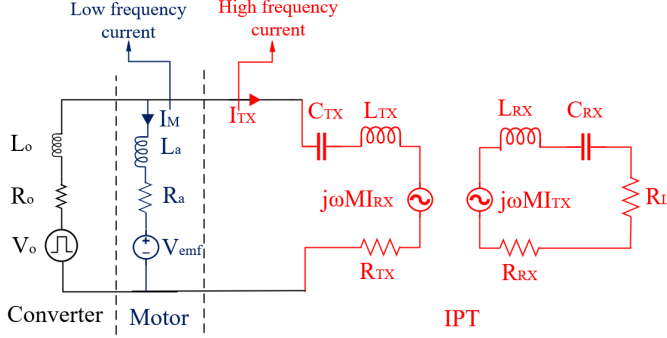

Fig. 7. Combined impedance model of the IPT system and the motor.

Input impedances of the motor and the IPT are calculated as in (6) and (7), which are shown in Fig. 8.

$$Z_{in-M} = j\omega L_a + R_a \quad (6)$$

$$Z_{in-IPT} = j\omega L_{TX} + \frac{1}{j\omega C_{TX}} + R_{TX} + \frac{j\omega M^2}{j\omega L_{RX} + \frac{1}{j\omega C_{RX}} + R_L + R_{RX}} \quad (7)$$

Fig. 8. Frequency response of the motor windings and the IPT coils.

V_o consists of both DC and harmonics of the switching frequency. The switching frequency and IPT resonant frequency are selected compatible, so the IPT has low-impedance only at the switching frequency. Besides, the motor is like a low-pass filter, which leads the DC component to pass and the switching harmonics to attenuate. Thus, the operating frequencies of the motor and IPT system are far from each other. Furthermore, controls of the motor and the IPT system can be decoupled as they behave like high-impedance loads at each other's

(a) Duty cycle-gain characteristic of IPT at 80 kHz. (b) Frequency-gain characteristic of IPT ($D = 0.5$).

(c) The iso-power lines of IPT through duty cycle and frequency.

Fig. 9. Simulation and experimental results of IPT voltage gain and power as a function of duty cycle and frequency.

operating frequencies thanks to the difference between their operating frequencies.

The motor current is controlled by varying the duty cycle, and it is independent of the switching frequency. In contrast, the gain of SS-IPT is changed by both the duty cycle and the frequency. The variation of the output voltage of SS-IPT (at $f_{sw}=80$ kHz) along with the duty cycle is shown in Fig. 9.a, and the variation of the output voltage with the switching frequency (with $D=0.5$) is shown in Fig. 9.b. On account of this, the power of IPT is plotted for different duty cycles and frequencies in Fig. 9.c, and it is observed to keep the IPT power constant by appropriate control of the duty cycle and the switching frequency.

Fig. 10. The block diagram of the control method of the combined motor and IPT system.

Consequently, the overall control method for the proposed system is given in Fig. 10. The motor controller decides on the duty cycle, considering the speed and torque. Then, the IPT controller adjusts the switching frequency to obtain desired output voltage of the IPT system, considering the duty cycle.

V. EXPERIMENTAL RESULTS

The experimental results were obtained using the setup, consisting of a DC motor with a GaN-based motor drive where

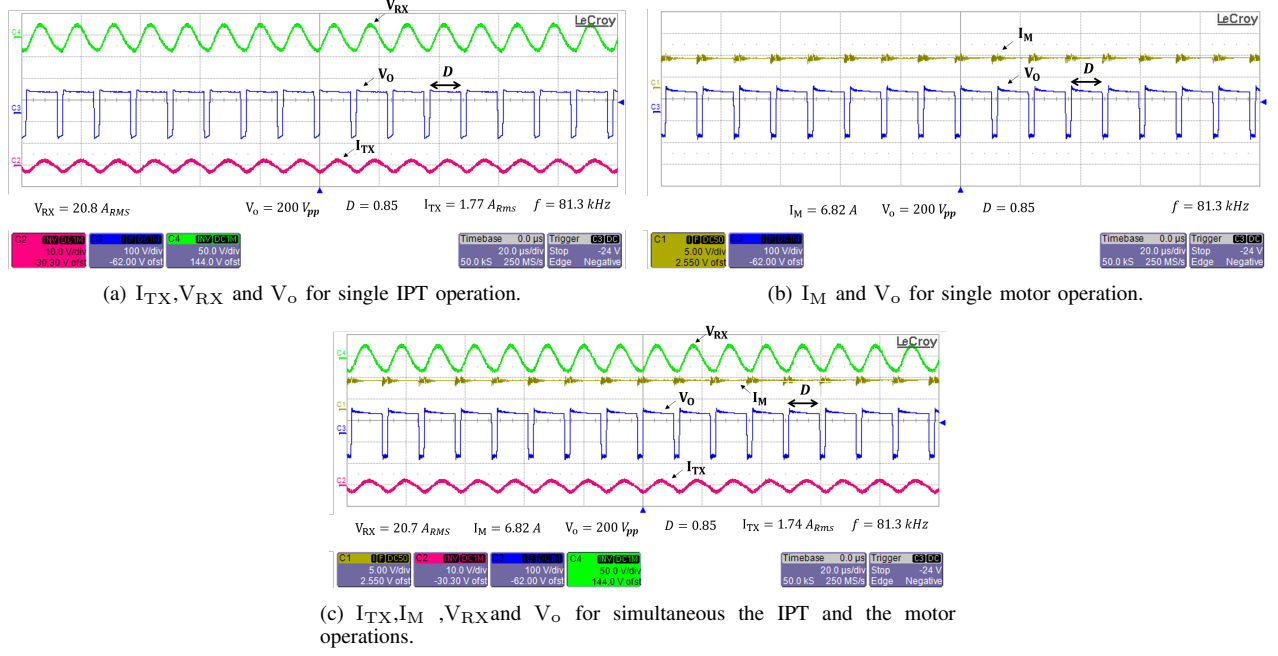

Fig. 11. Experimental results of the simultaneous operation of the proposed system with 100 V DC-link.

the parameters are given in Table IV, a generator, an IPT system where the parameters are given in Table III, a DC supply, and an oscilloscope. The setup is shown in Fig. 12.

TABLE IV
SYSTEM PARAMETERS OF THE SS-IPT

Transmitter inductance	205 μ H
Receiver inductance	51 μ H
Mutual inductance	40 μ H

Fig. 12. The illustration of experimental setup.

A. IPT Tests

IPT coils are wound, and the inductances are achieved as shown in Table IV. Firstly, the gain of $V_{o,1st}$ over the DC link voltage is obtained at $f_{sw} = 80 \text{ kHz}$. Then, the gain of the IPT system is attained at $D = 0.5$. Finally, the iso-power lines over the duty cycle and switching frequency are calculated. The simulation results were compared with the experimental results, shown in Fig. 9. The experimental results have an agreement with simulation results as expected.

B. Simultaneous operation of the IPT and the motor

In order to test the relation between the motor and IPT system, firstly, only the IPT system was connected to the FB converter, and the system operated at $f_{sw} = 81.3 \text{ kHz}$ with $D=0.85$. Fig. 11.a shows the output voltage of IPT (V_{RX}), the output voltage of FB converter (V_o) and the transmitter coil current (I_{TX}). IPT system transfers 54 W power at 20.8 V_{RMS} at this operation point. Secondly, only the motor was connected to the FB converter with the same duty cycle and switching frequency. Fig. 11.b shows the V_o and motor current (I_M). For this operation point, 480 W is delivered to the motor. Finally, the motor and IPT system were connected concurrently to the FB converter, and it was operated at the same conditions. In Fig. 11.c, V_{RX} , I_M , V_o , and I_{TX} are shown. It is observed that the motor current and the power delivered to the motor are not affected from the IPT system. In addition, the output voltage of the IPT stays constant with or without the motor. Although these initial results imply that the IPT system and the motor operations do not affect each other, the proposed system should be verified at different operating conditions.

C. Loss and Efficiency Measurements

One challenge of the proposed method is the additional high-frequency current components that need to be carried by the converter, which may create extra thermal stress.

TABLE V
EXPERIMENTAL RESULTS OF THE CONVERTER'S LOSS AND EFFICIENCY ANALYSIS WITH A CALORIMETER

Operation	Input Power (W)	Driver Losses (W)	Converter Output Power (W)	Efficiency (%)
Only IPT	67.6	7.3	60.3	89.2
Only Motor	457.1	12.8	444.3	97.2
IPT and Motor	522.2	14.1	508.1	97.3

Thus, the effect of the proposed system on drive losses needs to be examined. As these loss components are small and it is difficult to measure using electrical measurements, a calorimeter, which is regarded as more accurate than electrical loss calculations [20], is utilized. The total power loss in the drive for three conditions given in the previous subsection were measured, and they are presented in Table V.

The drive loss of simultaneous operation increases only 10% compared to the only motor operation, and so the system is feasible concerning thermal management.

D. The effect of transient load variations

In order to observe the transient response of the motor and IPT system, loads of each system were suddenly increased and decreased while keeping the other parameters constant.

Fig. 13. Experiment results for transient load variations of IPT and motor.

The motor and Rx currents are shown in Fig.13, and responses will be explained for each time interval as follows:

- $t_0 - t_1$: The motor is loaded with 105 W ($I_m = 1.9$ A), and the IPT system transmits 35 W ($I_{RX} = 1.7$ A_{RMS}).
- t_1 : The power of the motor is raised to 171 W.
- $t_1 - t_2$: I_m reaches to 2.9 A while I_{RX} is constant at 1.7 A_{RMS}.
- t_2 : The power of the motor is reduced to 105 W.
- $t_2 - t_3$: I_m is reduced to 1.9 A while I_{RX} is constant at 1.7 A_{RMS}.
- t_3 : The IPT system power is increased to 63 W.
- $t_3 - t_4$: While I_m is kept constant at 1.9 A, I_{RX} is increased to 2.4 A_{RMS}.
- t_4 : The IPT power is decreased to 35 W.
- $t_4 - t_5$: While I_m is constant at 1.9 A, I_{RX} is reduced to 1.7 A_{RMS}.

These tests prove the independent operation of IPT and motor. The operation of the IPT system is not disturbed by the motor load variations. The motor current is slightly affected (by a 5% overshoot or undershoot) at transients of the IPT system, but it quickly reaches the steady-state value as expected.

E. Tests under different operating conditions

In order to further investigate the operation range of the proposed system, six different operating points were selected. The duty cycles and switching frequency are adjusted to provide the desired power of the motor and IPT system as shown in Fig. 10. Table VI presents the test parameters for each case.

TABLE VI
SIMULTANEOUS OPERATION OF THE IPT AND THE MOTOR UNDER DIFFERENT OPERATING CONDITIONS.

	Cases					
	A	B	C	D	E	F
Operation Frequency (kHz)	95	90	90	95	90	90
Duty Cycle	0.6	0.75	0.75	0.6	0.6	0.6
Load Torque (N.m)	0.24	0.27	0.37	0.21	0.21	0.17
Motor Power (W)	125	179	244	109	110	89
IPT Power (W)	50	51	51	50	90	90

The power of the motor and IPT systems are shown in Fig 14. It is shown that the IPT power can be kept constant by frequency detuning for two different duty cycles as in the transition from A to B. In addition, the transitions from B to C and from E to F show that the IPT powers stay constant for two different motor loadings with the same D and f_{sw} . Moreover, the motor power is not affected by the f_{sw} variations, which is shown in the transition from D to E. It is concluded that the IPT system and motor can operate for different power ratings and loading, and their operations can be controlled separately by choosing the proper duty cycle and switching frequency combination.

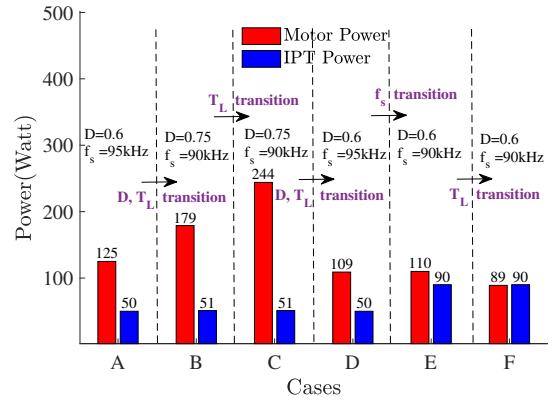

Fig. 14. The motor power and transmitted IPT power for different operating conditions.

VI. PERFORMANCE COMPARISON OF THE PROPOSED METHOD

Different power transfer techniques to rotating frames are studied in the literature, as shown in Table VII. There are several topologies, but they can be mainly divided into three categories, which are rotatory transformer (RT), capacitive

TABLE VII
COMPARISON WITH EXISTING STUDIES IN THE LITERATURE.

	[21]	[22]	[23]	[24]	[25]	[26]	[27]	[28]	[29]	[30]	[31]	This work
Frequency (kHz)	5	>650	250	100	848	50	1000	50	82.6	50	585	65
Power (W)	300	340	300	1000	100	231	10	500	3000	1000	10	50
Topology	RT	CPT	IPT	RT	CPT	IPT	IPT	IPT	IPT	IPT	IPT	IPT
Airgap (mm)	0.5	0.081	18	< 2	0.125	70	2	-	10	0.6	10	10
Diameter (mm)	171	76.2	120	-	160	95	46	100	100	-	50	110
Efficiency (%)	85	85	92-95	90	94	>82	80	>80	92	>95	81	89
Additional converter	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	No

power transfer (CPT), and inductive power transfer (IPT). RTs are used to transfer power for smaller airgaps (below 1 mm), but they have some drawbacks such as converter losses, lower switching frequencies, and bulky systems [21], [24]. CPTs are suitable to transfer power with higher frequency and medium power requirements over an even shorter airgap [22], [25]. IPTs can be used in a broad range of air gaps between 2mm to 70mm and can provide power ratings from 10W to 3kW [23], [26]–[31].

To sum up, such systems have a wide range of frequency, power, airgap, and size regarding the applications, and they usually have transfer efficiencies higher than 80%. However, such systems always require an additional converter to create high-frequency AC excitation. In the proposed system, the main advantage is utilizing the already existing motor drive for wireless power transfer, and it is shown that the frequency, power, airgap range is comparable with the existing studies.

VII. DISCUSSIONS OF THE STRESS ON THE DC-LINK CAPACITOR

Unlike a conventional motor drive, the addition of the high-frequency IPT current on the motor driver also increases the stress on the DC-link capacitor. Hence, adding the IPT system to a conventional motor drive may require minor modifications to the DC-link capacitance or to the type of capacitors. The current, supplied by the DC-link capacitors (I_{CAP}), is expressed as in (8) using switching functions (S_A and S_B) for the converter legs.

$$I_{CAP} = S_A(I_M + I_{TX}) - S_B(I_M + I_{TX}) - I_{in} \quad (8)$$

The motor and IPT currents (I_M and I_{TX}) are shown in (9). The switching harmonics of the motor current can be ignored (I_{Mdc}), and the first harmonic approximation (FHA) can be applied to the IPT current (I_{TXf}).

$$\begin{aligned} I_M &= I_{Mdc} \\ I_{TX} &= I_{TXf} \cos(2\pi f_s t - \Phi) \end{aligned} \quad (9)$$

The DC-link current harmonic components of the motor and IPT system can be obtained as in (10) and (11). Therefore, the DC-link current depends on the motor current, duty cycle, and Tx current.

$$I_{capM} = \sum_{k=1}^{\infty} \frac{4I_{Mdc}}{k\pi} \sin(k\pi D) \cos(2\pi k f_s t) \quad (10)$$

$$\begin{aligned} I_{capTX} &= -I_{TX} \cos(2\pi f_s t - \Phi) \\ &+ \sum_{k=1}^{\infty} \frac{2I_{TX}}{k\pi} \sin(k\pi D) \cos(2\pi(k+1)f_s t - \Phi) \\ &+ \sum_{k=2}^{\infty} \frac{2I_{TX}}{k\pi} \sin(k\pi D) \cos(2\pi(k-1)f_s t + \Phi) \end{aligned} \quad (11)$$

Since the capacitor current is affected by the motor current magnitude and duty cycle, a worst-case scenario was analyzed for simplicity. In this scenario, the motor current is initially zero at $D = 0.5$, and the motor power is linearly increased up to 500W at $D = 0.85$. The DC-link current can be calculated as in (10) when just the motor is connected. Then, the IPT system is connected parallel to the motor. The IPT system supplies 50W power while the duty cycle is varied from 0.15 to 0.85. The capacitor current, which stems from the IPT system, is calculated using (11). The capacitor currents for single and combined operation mode are shown in Fig. 15. The capacitor current changes with the duty cycles. Whereas the first switching harmonics are increased after the connection of the IPT system, it is observed that the higher harmonics are decreased.

(a) DC-link current under single motor operation. (b) DC-link current under combined motor and IPT operation.

Fig. 15. First, second, third and fourth harmonics of the DC link currents as a function of duty cycle.

After connecting the IPT system, the capacitor current increases from 1.45 A_{RMS} to 1.8 A_{RMS}, resulting in a 24% rise. Therefore, this may require minor modifications in capacitance if the IPT system is implemented to a conventional motor driver.

VIII. CONCLUSION

In this article, a novel IPT system to transfer power to rotating frames has been proposed. Unlike conventional systems, the proposed method does not require an extra converter, and the already existing motor driver is utilized to simultaneously run the motor and transfer power wirelessly. Hence, the complexity and cost are decreased. However, choosing a proper switching frequency is challenging since a high switching frequency increases the converter losses, and a low switching frequency increases the IPT coil size and cost. With the development of wide band-gap devices such as GaN and SiC, a sweet spot could be found, satisfying both requirements. Thus, the wide band-gap drives can be used as a single inverter for concurrent operations of motor and IPT systems. DC-link capacitor stress due to the extra IPT system has been investigated in this study, and it was concluded that the IPT system could be implemented to any conventional motor drive with maybe a slight modification to the DC-link capacitors. The proposed system, providing cost-reduced contactless slip rings, also can be utilized for auxiliary loads in other systems since it can be employed to other industrial motors, such as single-phase or multi-phase AC motors.
